## DEFORMABLE WELL SCREEN AND METHOD FOR ITS INSTALLAND

The invention relates to a well screen for preventing migration of solid particles, such as sand and other formation minerals, gravel and/or proppant, into a hydrocarbon production well.

More particularly, the invention relates to a well screen comprising at least one substantially tubular litter layer of which the sieve opening size to east the seasons.

filter layer of which the sieve opening size is tailored to the size of particles that are to be blocked by the screen.

Such a screen is known, for example, from UK patent such a screen is known, for example, from UK patent

specification 2115040. The known screen may further comprise outer and/or inner protective layers which are co-axial to the filler layer and which have a much larger sieve opening size than the filler layer or layers.

A problem encountered with the known screen is that woven metal wire and other filler sheets are fragile and can be easily squeezed and damaged during installation

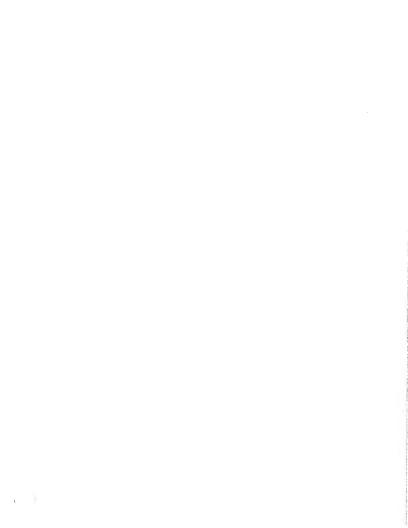

and use.

Only a minor deformation of the filter sheet may altready result in variation of the sieve opening which may hamper a proper performance of the screen.

Furthermore sand screens of the known type are typically made in a flat or tubular shape and are designed to remain in their original shape without substantial deformation during and/or after installation. However, in boreholes with an irregular surface and/or snarty bends this requires the use of a screen with a much smaller diameter than that of the wellbore. Such use of a smarty diameter surface and/or smaller diameter surface with a much small standard diameter screen will result in high fluid flowrates small diameter screen will result in high fluid flowrates
